# Chapter 4 Public Response to Hurricane Floyd In Northeast Florida

Prepared by

#### Earl J. Baker Hazards Management Group, Inc.

#### **Survey Method**

Approximately 600 telephone interviews were conducted in the seven counties of the Northeast Florida Regional Planning Council (Nassau, Duval, St. Johns, Flagler, Clay, Putnam, and Baker). The sample was stratified as follows:

- 1. 200 interviews in areas at risk to storm surge in category 1 hurricanes
- 2. 200 interviews in areas at risk to storm surge in stronger hurricanes
- 3. 100 interviews in areas of coastal counties not subject to inundation by storm surge
- 4. 100 interviews in non-coastal counties.

Evacuation zones defined in the most recent hurricane evacuation study for the region were used to identify the sampling areas. In Flagler the category 1 and 2 evacuation zones are the same. A copy of the questionnaire is included as Appendix I.

#### **Statistical Reliability**

Figures reported from surveys cited in this report are based upon samples taken from larger populations. The sample values provide estimates of the values of the larger populations from which the samples were selected, but usually are not precisely the same as the true population values. In general, the larger the number of people in the sample, the closer the sample value will be to the true population value. A sample of 200 will provide estimates which one can be 90% "confident" are within 4 to 6 percentage points of the true populations values, whereas a sample of 100 will provide the same degree of confidence of being within 5 to 8 percentage points of the true population values. With a sample of 50, one can be 90% "confident" of being within 7 to 11 percentage points of the actual population value, and a sample of 25 is 90% "accurate" only within 10 to 17

percentage points. With a sample of 50, one can be 90% "confident" of being within 7 to 12 percentage points of the actual population value. A sample of 25 is 90% "accurate" only within 10 to 17 percentage points.

The ranges (e.g., "10 to 17") stem from the fact that the reliability of an estimate depends not only on the size of the sample but also upon how much agreement there is among the responses. Having 90% of the respondents give a particular answer means almost everyone agreed. By the same reasoning, if only 10% gave a particular response, almost everyone agreed (i.e., 90% disagreed with the 10% but agreed with one another). The maximum disagreement is for the responses to be split 50-50. Thus, if 90% (or 10%) of a sample of 100 give a particular response, that estimate will be within 5 percentage points of the true population value 90% of the time. If 75% (or 25%) of a sample of 100 give a particular response, that estimate will be within 7 percentage points 90% of the time. If 50% of a sample of 100 give a particular response, that estimate will be within 8 percentage points 90% of the time.

Therefore, readers should keep in mind that some estimates provided in this report are more statistically reliable than others. This is particularly noteworthy in drawing conclusions about whether two survey results are "different" from one another. Differences of a few percentage points in sample results of 100 or less do not necessarily mean the populations from which the samples were drawn are different. When the aggregate samples are broken down into subgroups, the reliability of estimates for the subgroups suffers. Tables contain actual sample sizes used to calculate the values reported in the table. Sample sizes vary from table to table because not all questions were asked of all respondents (people who didn't evacuate weren't asked where they went, for example), some respondents refused to answer some questions, and in a few cases responses were invalid.

#### **Evacuation Participation Rates**

Evacuation, as used in the survey, refers to leaving one's home to go someplace safer. In the category 1 risk zone, 80% evacuated (Table 1). Emergency management officials in the largest county, Duval, ordered evacuation for the area east of the intracoastal waterway, which did not include category 1 risk areas along the St. Johns river in our sample. That might have accounted for part of the reason the participation rate was no higher. The "shadow" evacuation in other risk areas (i.e., evacuation from areas not told by officials to evacuate) was substantial, no doubt accounting for much of the evacuating traffic.

Table 1. Percent who left their homes in Floyd, by risk zone

	Cat 1	Other	Coastal	Non-Coastal		
	Surge Zone	Surge Zones	Non-surge	Counties		
	N=203	N=201	N=100	N=103		
Evacuated	80	44	30	24		

Most of the residents who did not evacuate gave the same reason: they felt their home would be safe, given the likely track and strength of the storm (Table 2). Some apparently observed the heavy traffic and decided not to leave. Some said they attempted to evacuate but gave up because of the traffic.

Table 2. Why Staved (Percent of Respondents)

Respondents were asked specifically whether anyone in their household had to work during Floyd and how that affected their evacuation (Tables 3, 4). At least a fourth said someone in the household had to work, and some said it either prevented some in the household from evacuating or delayed their departure.

Table 3. Someone in Household Had to Work in Floyd

Those who didn't evacuate were asked whether they would have left had they been convinced the storm was going to strike, and most said they would have (Table 5). Most also said they had made the necessary preparations to leave in case conditions worsened (Table 6).

In an attempt to separate the effect of messages disseminated by government officials via the media from the effect of other information heard via the media, respondents were asked which had the greater impact on their decision to evacuate. Information from officials had the greater impact, according to respondents (Table 8). Table 8. Greatest Influence to Leave (Percent of Respondents)

Interviewees were also asked whether they heard from officials – either directly or indirectly – that they should evacuate. Only in the category 1 risk area did a majority say they did (Table 9). Those who did hear evacuation notices were more likely than others to evacuate (Table 10). In the category 1 risk area, 97% of those who said they heard mandatory evacuation orders evacuated.

A majority of people living in all four risk areas believe they would be unsafe in a 125 MPH hurricane in their own homes (Table 11a). In all four risk zones people who perceived their homes to be vulnerable were more likely than others to evacuate (Table 11b).

Table 11a. Perceived Safety of Home from Wind and Water in 125 MPH Hurricane

## **Evacuation Timing**

Evacuation departures were fairly gradual, primarily during September 13 and 14, with the steepest portion of the response on the 14<sup>th</sup>. Forty percent of the eventual evacuees had left by 8 AM on the 14<sup>th</sup>. A hurricane watch was issued for the area at 11 AM on the 13<sup>th</sup>, followed by a warning at 5 PM later that day.

# **Cumulative Evacuation**

Northeast Florida Region

### **Use of Public Shelters and Other Refuges**

The great majority of evacuees went to the homes of friends and relatives or to hotels and motels (Table 12). Only in the non-category 1 surge zone did more than five percent of those interviewed say they went to public shelters.

Table 12. Types of refuge used (percent of evacuees)

Evacuation Destinations and Transportation Issues Most evacuees left their own county, going elsewhere in Florida, with a third going into Georgia (Tables 13, 14). The roughly 75% out-of-county evacuation was slightly higher than normal for the region.

Going out of county (beyond the surge inundation limits) was motivated by three main factors: the strength of the storm, the location of friends and family, and the lack of closer motels (Table 15). Information from government officials conveyed by the media was a larger influence than other media information (Table 16).

At least 75% of the evacuees from most risk areas eventually reached their destinations (Table 17). Of those who changed destinations, about half went someplace closer than anticipated and half when farther (Table 18). Traffic was the main reason for changing destinations (Table 19).

Most evacuees used interstate highways for at least part of their evacuation (Table 24). Those who used interstates in Floyd gave a mixture of future intentions concerning road use, but the overall tendency appeared to be flexibility, depending upon the circumstances (Table 25). More than 75% of the respondents said they were familiar with the roads in the area through which they evacuated (Table 26). Three-fourths also said they would be willing to use a different route than they would normally use if government officials urged them to do so to avoid congestion, even if the route took them

out of their way (Table 27). Only about 10% said they would be unwilling to comply with that sort of request by officials.

Almost half the respondents said it took them more than five hours to reach their destination, and about 15% said it took ten or more hours (Table 28). Only 20% to 30% expected the evacuation to take more than five hours, and fewer than five percent expected it to take ten or more (Table 29). When asked how long it was reasonable for an evacuation like Floyd's to take, most respondents gave times shorter than the actual evacuation but slightly longer than their original expectation (Table 30).

Most people thought the traffic delays were caused mainly by the sheer volume of traffic and the fact that too many people left at once (Table 31). Many also cited poor traffic management and advocated reversing lane directions. Most respondents said they would be willing to cooperate in a phased evacuation in which they would delay their departure for a few hours until people in a more dangerous location had begun their evacuation (Table 32).

Most evacuees did not cite specific difficulties experienced during the evacuation. Needing restroom facilities was most common, but a few ran out of gas or had mechanical breakdowns (Table 33). More than 35% of the evacuees said they heard about places where they could find shelter if they weren't able to reach their destinations (Table 34). Few changed their plans about seeking shelter as a result (Table 35). Most interviewees reported no difficulties returning from the evacuation (Table 36).

Vehicle use was typical of most evacuations, in which 65% to 75% of the available vehicles are used (Table 37). Few households required assistance in evacuating, and in most instances outside agencies were not required (Table 38).
